Practice04: Project

Mini Project

Write a console program to manage hospitalised patients only, based on their blood pressure and blood sugar levels.

Data

- names
- blood_pressures
- blood_sugars
- statuses
-

Hospitalisation Rules

- If BP > 140 and Sugar > 180 → status = "High Blood Pressure & High Blood Sugar" → add to lists
- Else if BP > 140 only → status = "High Blood Pressure" → add to lists
- Else if Sugar > 180 only → status = "High Blood Sugar" → add to lists
- Otherwise → print "No admission needed" and do not store the patient

Names must be unique. If a name already exists, print "This name already exists!" and do not add.

Mini Project

Menu (repeat until exit)

1. Add a patient
2. Display all admitted patients
3. Edit a patient's data
4. Search by patient name
5. Exit

Mini Project

1) Add

- Input: name, blood_pressure (int), blood_sugar (int)
- If name already exists in names → print "This name already exists!"
- Else apply Hospitalisation Rules and either add (with correct status) or print "No Hospitalisation needed"

2) Display

- If list is empty → print "No hospitalised patients!"
- Else print each record in order, e.g.
- 1: Sara | BP: 152 | Sugar: 190 | Status: High Blood Pressure & High Blood Sugar

Mini Project

3) Edit

- Input: name
- If not found → print "Patient not found!"
- If found → ask for new blood_pressure and blood_sugar, recompute status with Hospitalisation Rules:
  - If new status would be “No Hospitalisation needed” → remove the patient and print "Patient discharged"
  - Otherwise → update vitals and status (patient stays admitted)

4) Search

- Input: name
- If found → print the single record in the same display format
- Else → print "Patient not found!"

5) Exit

- End the program

Good luck

Never give up, never stop learning
